AN IMPROVED DEVICE

TECHNICAL FIELD

This invention relates to an improved device.

- In particular it relates to an improvement to a device that is used for the breaking or
- 5 weakening of material.

BACKGROUND ART

It is common practice in the construction or demolition industry to use hydraulic hammers in order to break up concrete, rock, hard ground, asphalt or unwanted structures for removal or further construction.

- 10 A large proportion of the material to be broken up consists of either concrete or asphalt. These materials have very different characteristic and therefore require different type of machinery or tool bits to break them up. Concrete is a very brittle material and can therefore be smashed by impaction. Asphalt is a ductile or 'plastic' material that tends to absorb a lot of the energy applied through impaction.
- 15 Accordingly, asphalt or similar materials need to be fractured. A finer blade will effectively slice, puncture or crack the material, therefore allowing demolition to be completed by cutting rather than hammering.

- Where asphalt is laid over concrete, as with many north American roadways, two types of hammer configurations can be required to complete the job, depending on
- 20 the thickness of the asphalt. This double layer can therefore mean the need for more than one demolition machine on a job, doubling the cost of demolition and creating down time for the concrete breaker while the asphalt breaker gets started and exposes the concrete.

Furthermore, ground that has been frozen by permafrost, for example in central Europe, can also have a more ductile or plastic nature. A blunt ended hammer will apply a force that will often be absorbed by the ground, resulting in either a punched hole and no fracture, or the ground will just bounce back due to the springiness of the peat beneath it. A finer blade tip is required to fracture the material. Again, either further machines are required, or the industry is delayed over the winter months. Additionally, the colder the conditions, the greater the likelihood of damage to the machinery due to temperature gradients across the hammer leading to thermal shock and resultant fracture.

- 10 The breaking up of ground that is frozen due to permafrost with current technology has proved to be virtually impossible and as such construction is limited to the warmer months that in some cases can be as short as ten to twelve weeks.

It would be an advantage to extend that construction time, even by a few weeks either side of the warmer months.

- 15 A typical drop hammer, being one type of demolition hammer device, consists of a heavy plug or column that is raised and then released. Gravity propels the plug or column towards the ground and the type of impact with the ground is determined by the shape of the face of the plug or column that connects with the ground.

- It would be an advantage to be able to easily vary the nature of fracture beneath the drop hammer so as to enable a single machine to operate in various conditions with different types of materials. However, any ability to vary the nature of fracture must be combined with the usual durability and overall strength required by the industry. It would be a limitation to produce a system that could be varied, but required high maintenance or a large period of downtime to implement.

- 25 All references, including any patents or patent applications cited in this specification

are hereby incorporated by reference. No admission is made that any reference constitutes prior art. The discussion of the references states what their authors assert, and the applicants reserve the right to challenge the accuracy and pertinency of the cited documents. It will be clearly understood that, although a
5 number of prior art publications are referred to herein, this reference does not constitute an admission that any of these documents form part of the common general knowledge in the art, in New Zealand or in any other country.

It is acknowledged that the term 'comprise' may, under varying jurisdictions, be attributed with either an exclusive or an inclusive meaning. For the purpose of this
10 specification, and unless otherwise noted, the term 'comprise' shall have an inclusive meaning - i.e. that it will be taken to mean an inclusion of not only the listed components it directly references, but also other non-specified components or elements. This rationale will also be used when the term 'comprised' or 'comprising' is used in relation to one or more steps in a method or process.

15 It is an object of the present invention to address the foregoing problems or at least to provide the public with a useful choice.

Further aspects and advantages of the present invention will become apparent from the ensuing description which is given by way of example only.

DISCLOSURE OF INVENTION

20 According to one aspect of the present invention there is provided a propelled rod with at least two end conditions

characterised in that

the position of the end conditions can be reversed when required.

According to another aspect of the present invention there is provided a drop

hammer assembly including a hammer configured with at least two end conditions characterised in that

the position of the end conditions can be reversed when required.

The term "propelled rod" in accordance with the present invention should be understood to mean an elongated shaft that is propelled toward a material in order to impart an impact.

The propulsion of such a shaft can be provided by gravity or by an accelerating means, or by a combination of the two.

In preferred embodiments, the propelled rod is an elongated shaft of either cylindrical or multi-faceted proportions that is able to be lifted in a substantially vertical direction prior to being released.

In some embodiments, gravity is used to provide the propulsion required to impart a force to the ground beneath the shaft.

In other embodiments, the propelled rod is also able to function in a direction away from the vertical, allowing it to break material that is above ground level. The introduction of an accelerating means allows the assembly to function without such a large reliance on gravity to propel the shaft toward the ground or material to be broken.

In preferred embodiments the shaft is a hammer for use in a drop hammer assembly or device, and for ease of reference the shaft is hereafter referred to as a hammer, although this should not be seen to be limiting in any way. The hammer is housed in a hammer housing, the internal workings of which enables the hammer to be lifted and released to impart force to the ground below the hammer.

It should be appreciated that it is an advantage of the present invention that the propelled rod is directly impacting the material desired to be broken, it is not striking an intermediate tool. This means that the system as a whole is simple and there are less moving parts to wear and fail over time. Each face can be reinforced, or built up after wear, and the hammers themselves can be replaced.

In some embodiments, a connecting means is provided between the hammer housing and the upper end of the hammer.

In preferred embodiments, the connecting means is able to undergo elastic deformation, thereby storing potential energy when being held in a tensioned state.

10 When the hammer is at the peak of its vertical movement, the connecting means is extended to a tensioned position. When the hammer is released, the potential energy stored in the connecting means in the form of tension is released and the hammer is accelerated toward the ground with greater energy than that provided by gravity alone.

15 US Patent No. 4,844,661 describes a drop hammer that utilises a reversing electromagnet to provide both lift and repulsion to the hammer. The electromagnet is engaged to raise the drop hammer to the top of its radius of movement. The electromagnet is then reversed and both gravity and the repulsion of the reversed electromagnet combine to accelerate the drop hammer to the ground, increasing the
20 force with which it hits the ground.

It is a limitation however of such a system that the type of ground or material to be broken by the hammer is determined by the shape of the hammer and this cannot be easily varied. For the device to work with brittle materials when it is configured to work with ductile materials, a considerable amount of down time would be needed to
25 fit a new hammer.

US Patent No. 5,248,001 describes a drop hammer that utilises a spring or springs within a drop hammer housing that are fully compressed when the hammer is at maximum vertical height before dropping. As the springs expand, the hammer is accelerated toward the ground again increasing the force at which the face of the hammer hits the region underneath.

It is a disadvantage of this system also that the type of material to be broken by the hammer is set by the shape of the end of the hammer and this cannot easily be varied. Accordingly, the hammer can only be used to break one type of material, be it brittle or ductile or the like, and a second machine would be needed on site for other materials.

The term 'condition' in accordance with the present invention should be understood to mean the shape of the surface of each end of the propelled rod, or the face. This shape could include a substantially flat face, a blade, a convex or concave cup or a point, however, these are listed by way of example only. For ease of reference throughout the specification, the term 'face' will be used to refer to the condition of each end of the propelled rod, however, this should not be seen to be limiting in any way as a blade or point is not usually referred to as having a face, although they are intended to be included here when the term 'face' is used.

In preferred embodiments, the hammer with at least two end faces is characterised in that the end faces are of different configurations.

In further preferred embodiments, the hammer has two faces, one at either end of the hammer where one of the end faces of the hammer could be of a substantially flat, wide face in order to provide a large region of impact beneath the hammer, imparting the ability to weaken or break larger regions of brittle material.

In further preferred embodiments, the other end face on the alternate end of the

hammer could be in the form of a blade, therefore allowing ductile or plastic material to be broken up.

It should be appreciated that the tip or end of the hammer could also be configured in other ways to be suitable for other types of material or demolition jobs. The tip
5 could, for example, be in the shape of a spike or sharp tip, instead of a blade, although this is listed by way of example only and should not be seen to be limiting.

While drop hammers configured to cope with various types of materials do exist, there does not appear to be a single drop hammer device that allows many types of materials to be broken by the same piece of machinery without significant amounts
10 of mechanical work or down time required to achieve this.

While it should be appreciated that some drop hammer devices could have the impact face at the end of the hammer removed in order to either renew the tip or face, or to alternate between a wide and narrow impact face, the amount of stress and strain placed on any nuts or bolts in that region would be immense. The
15 likelihood of bolts or the like shearing through failure due to high impact loads would be greatly increased. This can be disadvantageous when there are deadline pressures or limited access to repair resources.

Another problem inherent with changeable tips is that a certain degree of expertise is required in order to ensure the new tip is correctly mounted in its seat and tension
20 bolts having the appropriate tools to do so. Any misalignment of the new tip with the seat will result in rapid damage of the tip and loss of all precision of both the tip and seat mountings.

With regard to the present invention it should be appreciated that the nature of the material will determine the configuration of the hammer face. It is therefore
25 envisaged that should a machine be needed for a job with several types of material,

more that one double ended hammer could be supplied, as the hammer could be ejected and a whole new hammer put into the housing which has different faces.

The faces and tips of both the flat and bladed ends of the hammer could also be reinforced with material, or rebuilt due to wear down.

- 5 According to another aspect of the present invention there is provided a method of reversing the orientation of the hammer,

characterised in that

the hammer can be withdrawn, reversed and reinserted into its operating position.

- According to a further aspect of the present invention there is provided a method of
10 reversing the orientation of the hammer within the hammer housing, wherein the hammer has at least two end faces,

characterised in that

the hammer can be withdrawn from the hammer housing, the position of the end faces reversed and the hammer reinserted into its operation position.

- 15 It is an advantage of the present invention that the ability to remove the hammer from the hammer housing, reverse the direction of the hammer and reinsert it into the housing is a simple matter that could be undertaken by one person.

- It should be appreciated that hammer will have certain projections that enable it to be lifted within the hammer housing to its peak vertical position. In order to reverse
20 the orientation of the hammer, thereby exposing the alternate end of the hammer, those projections would need to be matched on the alternate side also.

In preferred embodiments, the additional projections would be positioned to the left or right of the original projection, on the same face.

However, it should be appreciated that the projections could be positioned on the alternate face, depending on the shape of the hammer housing, and the way in which the blade is reinserted into the housing on reversal.

Should the hammer be connected to a tensioned cable, that cable would need to be disconnected and then reconnected after re-orientation of the hammer, therefore also meaning that any connecting means would need to be matched on the alternate side of the hammer.

It should also be appreciated that as the hammer has varying end configurations, the means for raising the hammer would need to be positioned to any side of the hammer, not positioned at the end of it.

In preferred embodiments, the means for raising the hammer to its peak vertical position would be by a side chain and translation dog arrangement. The chain rotates around two sprockets positioned alongside the hammer. The chain has a translation dog that engages a projection positioned on the side of the hammer. As the chain is rotated, the hammer will lift as the projection affixed to the hammer rises with the rising of the translation dog. As the hammer reaches its maximum vertical lift height, the translation dog rotates around the chain sprocket and the hammer is released.

In further preferred embodiments, once the translation dog rotates around the sprocket and the hammer begins to fall, the rotation of the chain will mean the translation dog will come up against and engage the projection on the alternate side of the hammer, which is there in order to allow the direction of the hammer to be reversed. The translation dog will therefore impart a downward force to the hammer, increasing the acceleration of the hammer over a short distance due to the speed of rotation of the chain. Once the hammer picks up sufficient speed, gravity will increase the rate of decent of the hammer and the translation dog may no longer

engage the projection.

According to another aspect of the present invention there is provided a drive mechanism for a drop hammer which includes

a translation dog adapted to engage with at least two projections provided on a drop
5 hammer to move said drop hammer, and

a drive system associated with said translation dog, said drive system being adapted to move the translation dog,

the drive mechanism characterised in that

the translation dog is adapted to engage with a lifting projection provided on said
10 drop hammer to translate the drop hammer in a first direction, and adapted to engage with a separate drive projection provided on said drop hammer to translate the drop hammer in a second direction opposing said first direction.

According to another aspect of the present invention there is provided a drop hammer which includes

15 at least one lifting projection adapted to engage with a translation dog to translate the drop hammer in a first direction, and

at least one drive projection adapted to engage with a translation dog to translate the drop hammer in a second direction opposing said first direction

In preferred embodiments the drive system includes at least two sprockets, at least
20 one endless chain and at least one translation dog.

In some embodiments, the hammer may be operated using the chain and translation dog drive down arrangement at an angle up to 120 degrees away from the vertical axis. In this case, the down stroke of the hammer becomes an upstroke

and the effect of gravity is negative. Accordingly, the hammer and translation dog drive-down system become a drive-up system and essential for the hammer to function.

Throughout the specification the term 'first direction' may be associated with an upward movement of the hammer when the drop hammer devices is operated in a substantially vertical position. This should not be seen to be limiting however as in the case where the drop hammer device is operated at an angle above the horizontal, that first movement becomes a downward movement in effect, but the overall intention of the term should be interpreted as being the same.

Furthermore, the term 'second direction' may be associated with a downward movement of the hammer, or in a direction opposite to that of the first movement, although again, as above, this should not be seen to be limiting in any way.

Throughout the specification reference is also made to a 'chain' or 'drive system' however these terms are listed by way of example only and should not be seen to be limiting in any way as the means for moving the translation dog could be by a ram drive where the translation dog pivots up and down with the movement of the ram drive.

Furthermore, the term 'chain' is listed by way of example only and should not be seen to be limiting in any way as belt drive could also be used to move the translation dog around the sprockets.

In preferred embodiments the lift projection is a protrusion that is attached to the hammer, is configured to engage the translation dog and is positioned so as to be engaged by the translation dog as it moves past the lift projection. The translation dog will engage or abut the lift projection and cause the hammer to lift. When the translation dog rotates over the upper sprocket, the lift projection is released and the

hammer will released in order to fall.

It should further be appreciated that the lift projection may be detachable and therefore replaceable as it wears.

In other preferred embodiments the drive projection is a protrusion that is also
5 attached to the hammer on the alternate side to the lift projection in such a position
so as to be engaged by the translation dog as it moves past the drive projection on
the downward stroke of the hammer. The translation dog will engage or abut the
drive projection and cause the hammer to be driven in the direction desired, which is
usually downward. The drive projection will be released when the speed of decent
10 of the hammer increases beyond the speed of rotation of the chain.

In some embodiments when the drop hammer device is being operated in a position
above horizontal, the translation dog may remain engaged with the drive projection
until it rotates around the lower sprocket.

It should further be appreciated that the drive projection may be detachable and
15 therefore replaceable as it wears.

In preferred embodiments there are two sprockets that associated with the drive
system. Throughout the specification those sprockets are often referred to as upper
and lower sprockets. It should however be appreciated that those terms are relative
to the position of the hammer when in operation and as such, the term upper
20 sprocket will refer to the sprocket at the upper end of the drop hammer device when
it is being operated in a substantially vertical position. This will also apply to the
term 'lower sprocket' as well and should however not be seen to be limiting in any
way.

The translation dog may be fixed to the chain, and chain may rotate around the
25 sprockets at speed. Accordingly, the translation dog can engage a lifting projection

when the translation dog is moving. The lifting projection can be attached to the hammer and as such, the hammer will be moved in the direction that the translation dog is travelling and, when the hammer is being operated in a position below horizontal, the hammer will rise.

- 5 When the translation dog reaches the top sprocket and is rolled over same, the lifting projection is released. The hammer will continue to travel until the force of gravity stops the motion of the hammer and the hammer will then change direction.

It should be appreciated that at the moment when the translation dog engages the drive projection on the down stroke of the hammer, the hammer may be moving in
10 an upward or, downward direction, or may even be stationary, depending on the speed of the chain, and accordingly, the speed of travel of the translation dog over the sprocket.

In some embodiments, if the speed of rotation of the chain were slower than the time taken for the hammer to reach its maximum height (where the downward force
15 due to gravity is equal and opposite to the upward motion of the hammer), then the translation dog could engage the drive projection while the hammer were already beginning its downward motion.

It should therefore be appreciated that as the translation dog engages the drive projection, some stress and wear could be imparted to the chain, the surface of the
20 translation dog engaging the projection and the projection itself. Furthermore, a knock or jolt may be noticeable as the translation dog engages the drive projection.

In other embodiments, if the speed of rotation of the chain were faster than the time taken for the hammer to reach its maximum height (when operated in a position below horizontal) then the translation dog would reengage the projection while the
25 hammer was still moving in an upward direction.

It should be therefore appreciated that the upward motion of the hammer could be interrupted by the translation dog engaging the drive projection after rotating over the upper sprocket. Such an interruption of the upward motion of the hammer could place undue stress on the chain, the translation dog and the projection, causing
5 increased deterioration of the drop hammer device.

In preferred embodiments, the speed of rotation of the chain with translation dog attached may be matched to length of time taken for the hammer to reach its peak movement and come to instantaneous rest before beginning to fall. The translation dog could then engage the drive projection as the hammer were beginning to gain
10 momentum in the downward direction, and the engagement of the translation dog against the drive projection could be smooth in motion causing a minimum amount of wear to the translation dog, the chain and the drive projection.

It should be appreciated that same situation would occur, regardless of the orientation of the hammer away from use in a vertical position. Accordingly, while
15 reference in the specification may be made to the hammer reaching its maximum height, one skilled in the art would recognise that this term should not be seen to be limiting. When the drop hammer device is operated near or above the horizontal, the hammer would reach a maximum distance away from the material to be broken.

Accordingly, an ideal location could be identified as to where to place the projection
20 to be engaged by the translation dog on the downward stroke. If the chain were run at a constant high speed, being approximately 2.5 metres/second, the hammer would be released and want to continue its travel upwards by approximately another 300mm due to momentum imparted by the lift speed. Before the hammer had stopped the upward motion, the translation dog would have already proceeded over
25 the top of the upper sprocket and be on the way down, therefore engaging the projection on the hammer while the hammer were still travelling upward, and in

some cases the hammer may have only travelled 100mm of the 300mm upward motion.

Such an engagement while the hammer was still in an upward motion could cause a high level of impact, potentially damaging the drop hammer device.

- 5 Accordingly, the speed of the sprocket can be slowed momentarily so that the translation dog's travel around the upper sprocket may be reduced from approximately 120 milliseconds to approximately 70 milliseconds at full speed. The slowing of speed of rotation of the chain may have the advantage of allowing the hammer to complete its upward motion and reach the point of zero motion before
- 10 the translation dog engages the projection.

It should however be appreciated the slowing of the sprocket by momentarily reducing its speed of rotation is listed by way of example only and should not be seen to be limiting in any way. Other means of matching the position of the translation dog to the motion of the hammer may be utilized and such would be

15 recognised by someone skilled in the art.

According to another aspect of the present invention there is provided a method of adjusting the speed of operation of a drive mechanism such as describe above,

characterised by the steps of

- 20 a) determining the position of a translation dog provided with said drive mechanism, and
- b) changing the speed of movement of the drive system when the translation dog is disengaged from a lift projection associated with a driven drop hammer.

In preferred embodiments the drive system is driven by a pressurised hydraulic fluid.

In further preferred embodiments the speed of the drive system is modified through changing the pressure of the hydraulic fluid used to drive same.

It should be appreciated that by adjusting the hydraulic flow to the sprocket drive, the sprocket will pause or slow in speed of rotation briefly, imparting a change in speed to the chain, thereby allowing the speed of the chain to be matched to the rise and fall of the hammer. This change in speed of the chain provides the ability to match the travel of the hammer to the drive down of the translation dog. Therefore, the hammer may be driven down from the highest point possible and thus maximum benefit from gravity may be gained for the remainder of the down stroke of the hammer when the hammer is used in a position below the horizontal line.

This is an advantage in that if the hammer is run at a higher rate, then the matching of the downward movement of the translation dog can be matched to the point of instantaneous zero movement of the hammer regardless of speed, allowing the drop hammer device to be optimally operated.

Furthermore, by optimising the timing of the downward movement of the translation dog to the instantaneous moment of the hammer, an increase of up to 100% in power may be achieved when using the same weight hammer and the same number of blows per minute.

Alternatively, if the blow per minute rate is increased by 100% and the weight of the hammer halved, the same power as a hammer not utilising a drive down chain, translation dog and projection combination may be achieved.

Additionally, when the drop hammer device is operated at low angles from the horizontal, or even at substantially horizontal, an increase in power of 40% may be achieved, in comparison with no power at all with a standard hammer device not utilising the drive down chain, translation dog and projection combination.

In further embodiments, a spring to arrest the movement of the hammer at the top of the stroke could also be utilized in the drop hammer device. The spring could make the moment of contact between the translation dog and the projection on the downward stroke of the hammer more reliable when the drop hammer device is
5 operating at different angles or at varying stages of lubrication.

A hammer needs to be regularly greased in order to operate optimally. A reduction in grease causes a slowing of the blows per minute the hammer can achieve due to friction. A newly greased hammer will travel higher on the upward stroke when released from the translation dog than a dry hammer and as such, an inconsistency
10 is introduced in the time taken for the hammer to slow down after being released from the translation dog.

In preferred embodiments, the introduction of a spring to the region above the maximum height of the hammer may help to arrest the upward motion of the hammer, once the hammer has been released from the translation dog, providing a
15 consistency of operation regardless of the level of grease on the drop hammer device.

In other embodiments, when the hammer is being operated at a large angle from the vertical, particularly in a newly greased state, there is very little gravity to arrest the movement of the hammer after the translation dog releases it. Accordingly, the
20 hammer will have enough force to potentially damage the upper end of the drop hammer casing, potentially even punching through the end of the drop hammer casing in a worst-case scenario. The introduction of a spring to the drop hammer device as described above may arrest the motion of the hammer and therefore avoid damage to the upper end of the drop hammer casing.

25 Accordingly, the combination of the chain, translation dog and projection with the spring may provide the ability for the drop hammer device to be utilised at high

angles, even above the vertical. This is a distinct advantage over the prior art and allows entire buildings or the like to be broken up by one machine.

In other embodiments, the hammer housing can have a number of posts or uprights positioned near the exit point of the hammer from the housing that are cushioned.

- 5 The cushioning would lessen the impact of the projection of the side hammer housing and potentially lengthen the lifetime of the hammer itself. The cushioning could be replaced over time as it wore out.

It should be appreciated that the hammer would be positioned at an appropriate height above the material or ground to be broken and as such, that ground would
10 receive the majority of the impact force and not the projection or cushioning. Accordingly, the cushioning will wear out, but at any cushioning system would be designed for easy removal and replacement with little down time.

The advantage of having a drop hammer device with two differing faces that can be reversed with ease is that the same piece of equipment can be used on sites where
15 varying types of material are required to be broken. This reduces the cost of a job requiring both brittle concrete and ductile asphalt or the like to be broken. It also enables the operator to switch easily between both types of impacting at short notice.

The ability of a drop hammer device to be applicable in varying situations is also an
20 advantage in that the drop hammer device described herein does not return the impact vibration back to the excavator and therefore the operator. As the hammer is not physically connected to the housing, unless by the tensioned means alone, the impact of the hammer does not impart any vibration to the housing. Accordingly, the driver is not exposed to high levels of vibration and therefore the job becomes more
25 tolerable over extended periods of time. Additionally, the driver does not welcome a break when differing types of material are revealed and needed to be broken and a

new machine required. Instead, the comfort to the operator is high, and the damage to the excavator itself from extensive vibration is non-existent.

A further advantage of a drop hammer device that includes a drive down means is that the pressure of impact can be increased substantially, allowing the same machine to increase its workload. Additionally, if the weight of the hammer is halved, the speed of impacting can be increased while maintaining the same impact pressure. This also provides an improvement over the prior art and would allow a single machine to increase work capacity or type of material applicable for impact by a drop hammer device.

Furthermore, the addition of the drive down means is that the drop hammer can be operated at angles away from substantially vertical. The drop hammer may even be used at angles up to 120 degrees away from the vertical, meaning that the hammer is operating not as a drop hammer but as a drive hammer, allowing one machine to do the job of both a drop hammer device and a jack hammer or the like.

A further advantage of the present invention is that the ability to change the speed of the rotation of the chain to allow the translation dog to engage the drive projection is the ideal position is that wear of the drop hammer device is minimised and the smoothness of operation is maximised, allowing an operator to handle longer working times with full concentration.

Furthermore, variance in use of the hammer brought about by greasing of the hammer is minimised by inclusion of the spring. Variations in operation are also minimised, reducing wear and variation in responsiveness of the drop hammer device, allowing for a more consistent operation of the device.

BRIEF DESCRIPTION OF DRAWINGS

Further aspects of the present invention will become apparent from the following

description which is given by way of example only and with reference to the accompanying drawings in which:

Figure 1 is a diagrammatic illustration of a preferred embodiment of the present invention; a

5 Figure 2 is a diagrammatic representation of a preferred embodiment of the present invention showing the side on view of the drop hammer with lifting means, and

Figure 3 is a close-up diagrammatic representation of a side view of the drop hammer showing the cushioning means and rotating chain.

10 **BEST MODES FOR CARRYING OUT THE INVENTION**

With reference to figure 1, there is illustrated a drop hammer (1), encased within a hammer housing (2) which is attached to a hydraulic excavator generally indicated by arrow 3.

15 With respect to figure 2 there is shown a close-up of a drop hammer device generally indicated by arrow 4. The drop hammer device (4) consists of a hammer (1) with a dull end (5) and a sharp end (6), a projection (7), a raising mechanism generally indicated by arrow 8, the raising mechanism in the form of a rotating chain (9), with two cogs (10 a and b), a hydraulic activating means (11) and a hammer housing (2).

20 With respect to figure 3 there is shown a side view of the hammer (1) with the rotating chain (9), the two end sprockets (10 a and b) which the chain (9) rotates around, a translation dog (12) which engages the projection (7) on the hammer (1).

Also shown in figure 3 is the cushioning means (13) that the hammer (1) can rest against when situated in its lowest vertical position.

When the drop hammer (1) is operating, the rotating chain (8) with translation dog (12) rotates.

The translation dog (12) engages the projection (7) situated on the side of the hammer perpendicular to the rotating chain (9).

- 5 As the chain (9) rotates, the translation dog (12) rises, lifting the projection (7) which in turn raises the hammer (1).

When the projection (7) rises to a point level with the upper sprocket (10a), the translation dog (12) rotates over the top of the upper sprocket (10a) and releases the projection (7), allowing the hammer to fall.

- 10 When the hammer (1) has completed its fall, the translation dog (12) positioned on the rotating chain (9) will then engage the projection (7) and repeat the vertical lift.

- Also shown in figure 3 is the cushioning means (13) that the hammer (1) can rest against when situated in its lowest vertical position. If the hammer (1) is not in use, the projection (7) will rest against the cushioning means (13) so that the hammer
15 can either be moved or transported without banging against the hammer housing, or damaging the rotating chain or the like.

- Not shown is the tensioned means that can be attached to a point just below the upper end of the drop hammer (1). As the hammer (1) rises to its upper vertical limit, the tensioned means is stretched. When the translation dog (12) is rotated
20 and the projection (7) released, the hammer (1) is pulled in a downward direction, accelerating the hammer (1) into the ground due to the release of the tensioned means.

Aspects of the present invention have been described by way of example only and it should be appreciated that modifications and additions may be made thereto without

departing from the scope thereof.

CLAIMS:

1. A drop hammer assembly including a hammer configured with at least two end conditions

characterised in that

the position of the end conditions can be reversed when required.
2. A drop hammer assembly as claimed in claim 1 wherein the hammer is an elongated shaft that is propelled toward a material in order to impart an impact.
3. A drop hammer assembly as claimed in either claim 1 or claim 2 wherein the propulsion of the hammer is provided by gravity.
4. A drop hammer assembly as claimed in either claim 1 or claim 2 wherein the propulsion of the hammer is provided by an accelerating means.
5. A drop hammer assembly as claimed in either claim 1 or claim 2 wherein the propulsion of the hammer is provided by a combination of gravity and an accelerating means.
6. A drop hammer assembly as claimed in any one of the previous claims wherein the hammer is cylindrical
7. A drop hammer assembly as claimed in any one of claims 1 to 5 wherein the hammer is multifaceted.
8. A drop hammer assembly as claimed in any of the previous claims wherein the hammer end conditions are different.
9. A drop hammer assembly as claimed in claim 9 wherein an end condition of

the hammer forms a substantially flat surface.

10. A drop hammer assembly as claimed in claim 9 wherein an end condition of the hammer forms a blade.
11. A drop hammer assembly as claimed in claim 9 wherein an end condition of the hammer forms a substantially convex surface.
12. A drop hammer assembly as claimed in claim 9 wherein an end condition of the hammer forms a substantially concave surface.
13. A drop hammer assembly as claimed in claim 9 wherein an end condition of the hammer forms a spike.
14. A drop hammer assembly as claimed in claim 9 wherein each end condition of the hammer is selected for use depending on the material to be impacted.
15. A drop hammer assembly as claimed in any of the previous claims wherein the hammer is substantially enclosed within a housing.
16. A drop hammer assembly as claimed in claim 9 wherein the housing includes a mechanism adapted to lift the hammer.
17. A drop hammer assembly as claimed in any of the previous claims wherein the hammer includes at least one protrusion
18. A drop hammer assembly as claimed in any of the previous claims wherein the hammer includes protrusions on opposing sides.
19. A drop hammer assembly as claimed in either claim 18 or claim 19 wherein the protrusion is configured to be engaged by the mechanism adapted to provide lift to the hammer.

20. A drop hammer assembly as claimed in any one of the claims 17 to 20 wherein the mechanism configured to lift the hammer includes at least two sprockets, and at least one dog and a chain.
21. A drop hammer assembly as claimed in claim 20 wherein a dog is attached to a chain.
22. A drop hammer assembly as claimed in either claim 20 or claim 21 wherein a dog is adapted to engage the protrusion.
23. A drop hammer assembly as claimed in any one of claims 20 to 22 wherein a chain is adapted to be rotated around said at least two sprockets.
24. A drop hammer assembly as claimed in any one of claims 20 to 23 wherein the sprockets, dog and chain are aligned substantially parallel to the hammer.
25. A drop hammer assembly as claimed in any one of claims 20 to 23 wherein the sprockets, dog and chain are aligned substantially perpendicular to the hammer.
26. A drop hammer assembly as claimed in any of the previous claims wherein the hammer is adapted to impact the material to be broken directly.
27. A drop hammer assembly as claimed in any of claims 15 to 26 which includes a connecting apparatus between the hammer and the hammer housing.
28. A drop hammer assembly as claimed in claim 27 wherein the connecting apparatus is able to undergo elastic deformation.
29. A drop hammer assembly as claimed in either claim 27 or claim 28 wherein

the connecting apparatus is detachable.

30. A method of reversing the orientation of a hammer as claimed in any of the previous claims located within a hammer housing, said hammer,
- characterised by the steps of
- a) withdrawing the hammer from the housing,
 - b) reversing the direction of the hammer, and
 - c) reinserting the hammer into its operating position.
31. A method of reversing the orientation of the hammer within the hammer housing as claimed in claim 30, wherein the hammer has at least two end conditions,
- characterised in that
- the hammer is withdrawn from the hammer housing, the direction of the hammer reversed and the hammer reinserted into its operation position.
32. A drop hammer assembly, substantially as herein described with reference to figures 1 to 3.
33. A method of reversing the orientation of a hammer substantially as herein described.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/NZ2003/000235

A. CLASSIFICATION OF SUBJECT MATTER

Int. Cl. 7: E02D 7/08, E04G 23/08, E01C 23/12, E21B 1/02

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

Dwpi: E01C 23/12, E02D 7/06, 7/08, E04G 23/08, E21B 1/02, 1/12, 4/08, B25D 1/14, B66F 15/00

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X Y	US 4813494 A (BEARD et al) 21 March 1989 The whole document	1-15, 17, 26-33 16, 18-25
X Y	US 3568657 A (GUE) 9 March 1971 The whole document	1-15, 17, 26-33 16, 18-25
X Y	US 5699864 A (DVORAK et al) 23 December 1997 The whole document	1-15, 17, 26-33 16, 18-25
X Y	AU 16544/95 A (BROWN) 31 October 1996 The whole document	1-15, 17, 26-33 16, 18-25

Further documents are listed in the continuation of Box C

See patent family annex

* Special categories of cited documents:	
"A" document defining the general state of the art which is not considered to be of particular relevance	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"E" earlier application or patent but published on or after the international filing date	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"O" document referring to an oral disclosure, use, exhibition or other means	"&" document member of the same patent family
"P" document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search
